Technical Field

This invention relates to benzimidazole compounds and their pharmaceutically acceptable salts, and pharmaceutical compositions containing such compounds. These compounds and compositions have cyclooxygenase-2 inhibitory activities, therefore they are useful as agents for treatment of inflammatory diseases 15 of a mammalian subject, especially a human subject.

Background Art

Nonsteroidal anti-inflammatory drugs (NSAIDs) are widely used in treating pain and the signs and symptoms of arthritis because of their analgesic and anti-inflammatory activity. It is accepted that common NSAIDs work by blocking the 20 activity of cyclooxygenase (COX), also known as prostaglandin G/H synthase (PGHS), the enzyme that converts arachidonic acid into prostanoids. Prostaglandins, especially prostaglandin E2 (PGE₂), which is the predominant eicosanoid detected in inflammation conditions, are mediators of pain, fever and other symptoms associated with inflammation. Inhibition of biosynthesis of 25 prostaglandins has been a therapeutic target of anti-inflammatory drug discovery. The therapeutic use of conventional NSAIDs is, however, limited due to drug associated side effects, including life threatening ulceration and renal toxicity. An alternative to NSAIDs is the use of corticosteroids, however, long term therapy can also result in severe side effects.

30

Recently, two forms of COX were identified, a constitutive isoform (COX-1) and an inducible isoform (COX-2) of which expression is upregulated at sites of inflammation (Vane, J. R.; Mitchell, J. A.; Appleton, I.; Tomlinson, A.; Bishop-Bailey, D.; Croxtoll, J.; Willoughby, D. A. Proc. Natl. Acad. Sci. USA, 1994, 91, 2046). COX-1 is thought to play a physiological role and to be responsible for gastrointestinal and

renal protection. On the other hand, COX-2 appears to play a pathological role and to be the predominant isoform present in inflammation conditions. A pathological role for prostaglandins has been implicated in a number of human disease states including rheumatoid and osteoarthritis, pyrexia, asthma, bone resorption, 5 cardiovascular diseases, nephrotoxicity, atherosclerosis, hypotension, shock, pain, cancer, and Alzheimer disease. The NSAIDs currently on market inhibit both isoforms of COX with little variation for selectivity, explaining their beneficial (inhibition of COX-2) and deleterious effects (inhibition of COX-1). It is believed that compounds that would selectively inhibit the biosynthesis of prostaglandins by 10 intervention of the induction phase of the inducible enzyme cyclooxygenase-2 and/or by intervention of the activity of the enzyme cyclooxygenase-2 on arachidonic acid would provide alternate therapy to the use of NSAIDs or corticosteroids in that such compounds would exert anti-inflammatory effects without the adverse side effects associated with COX-1 inhibition.

15 A variety of imidazole compounds are known and are disclosed in several patent applications. Specifically, Japanese Kokai (laid-open) Publication number S49-81369 discloses 1-benzyl-benzimidazole compounds as anti-inflammatory agents. Japanese Kokai (laid-open) Publication Number S59-75257 and H06-194780 disclose a variety of benzimidazole compounds as electrophotographic 20 materials.

General Synthetic Method

A compound of formula I may be prepared by any synthetic procedure applicable to structure-related compounds known to those skilled in the art. The following representative examples as described in Schemes I-VI are illustrative of the invention in which, unless otherwise stated, Ar, R¹, R², R³, X¹, X², m and n are as defined herein before. For the synthesis of compounds of related-structure to compounds of the present invention, see "Benzimidazoles and Congeneric Tricyclic Compounds" in *Heterocyclic Compounds*, Vol. 40, Preson, P. N. Ed., John Wiley & Sons, NY, 1981.

Scheme A

5 For example, the compound of formula I may be prepared according to the reaction outlined in Scheme A. In the instant example, a phenylenediamine compound of formula 1 is reacted with a compound of formula 2 wherein the group Q is defined such that the compound of formula 2 is, but not limited to, a carboxylic acid, a carboxylic acid ester, a carboxamide, a carboxylic acid anhydride, a carboxylic acid chloride, an orthoester, an imino ether or a carboxaldehyde. The reaction may be conducted in the presence or absence of a reaction inert solvent. Preferred reaction inert solvents include, but are not limited to, benzene, toluene, xylene, pyridine, 1,2-dichloroethane, o-dichlorobenzene, nitrobenzene, dichloromethane and the like. Preferably, the reaction is conducted in the presence
10 of a promoter such as hydrochloric acid, polyphosphoric acid, phosphorous pentoxide, phosphorous oxychloride, polyphosphoric acid ethyl ether, polyphosphoric acid trimethylsilyl ether, p-toluenesulfonic acid, zinc (II) chloride and the like. When a compound of formula 2 is carboxaldehyde, the reaction may be conducted in the presence of an oxidant such as cupric acetate, chloranil, and the like. Reaction
15 temperatures are preferably in the range of -40°C to 250°C, more preferably 10°C to 200°C, usually in the range of room temperature (e.g., 25°C) to 200°C, but if
20

necessary, lower or higher temperature can be employed. Reaction times are, in general, from 1 minute to several days, preferably from 20 minutes to 1 day. Alternatively, the reaction may be conducted in a sealed tube or an autoclave at medium to high pressure to accelerate it, preferably in the range of 2 to 150 kg/cm².

5

Scheme B

10 Alternatively, the compounds of formula I may be prepared by a two step procedure from phenylenediamine compounds of formula 1 via the (N-acylamino)phenylamine compounds of formula 4 as shown in Scheme B. In the first step, a phenylenediamine compound of formula 1 is reacted with a compound of formula 3, wherein Z is selected from halo, -OH, -OR (R is C₁-C₄ alkyl), -NH₂ or -OC(O)CR²=CR³-R¹, by conventional methods known to those skilled in the art to

15

form amides of formula 4. For example, when a compound of formula 3 is carboxylic acid (i.e., Z is OH), the reaction is preferably conducted in the presence of a coupling reagent such as 1-(dimethylaminopropyl)-3-ethylcarbodiimide (WSC), N,N'-dicyclohexylcarbodiimide (DCC), carbonyldimidazole, cyanophosphonic acid diethyl ester or the like. Preferred reaction-inert solvents include, but are not limited to, acetone, acetonitrile, dichloromethane, N,N-dimethylformamide, N,N-dimethylacetamide, dimethylsulfoxide, dioxane, tetrahydrofuran and pyridine. Reaction temperatures are preferably in the range of -40°C to 250°C, more preferably 10°C to 200°C, usually in the range of room temperature (e.g., 25°C) to 200°C, but if necessary, lower or higher temperature can be employed.

In the next step, the compounds of formula I are provided by cyclization of the compounds of formula 4. The reaction may be conducted in the presence or absence of a reaction inert solvent. Preferred reaction inert solvents include, but are not limited to, benzene, toluene, xylene, pyridine, 1,2-dichloroethane, o-dichlorobenzene, nitrobenzene, dichloromethane and ethanol. Preferably, the reaction is conducted in the presence of a promoter such as of hydrochloric acid, polyphosphoric acid, phosphorous pentoxide, phosphorous oxychloride, polyphosphoric acid ethyl ether, polyphosphoric acid trimethylsilyl ether, thionyl chloride and *p*-toluenesulfonic acid. Alternatively, the compounds of formula I may be prepared by the reaction of a suitable aldehyde with a suitable phosphonium (Maryanoff, B. E.; Reitz, A. B. *Chem. Rev.* 1989, 89, 863) or a dialkyl phosphonate salt (Seguineau, ; Villieras, *Tetrahedron Lett.* 1988, 29, 477) as shown in Schemes E and F, wherein P is a suitable phosphonium or dialkyl phosphonate salt. The starting material of formulae 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11 and 12 may be obtained by conventional procedures known to those skilled in the art. The preparation of such starting materials is described within the accompanying non-limiting examples which are provided for the purpose of illustration only. Alternatively, requisite starting materials may be obtained by analogous procedures, or modifications thereof described hereinafter.

The products which are addressed in the aforementioned general synthesis and illustrated in the experimental examples herein may be isolated by standard methods and purification can be achieved by conventional means known to those skilled in the art, such as distillation, recrystallization and chromatography techniques.

The compounds of the present invention which contain one or more double bonds and/or asymmetric centers are capable of existing in various stereoisomeric forms. All individual forms and mixtures thereof, are included within the scope of the invention. The various isomers can be obtained by standard methods. For example, *cis/trans* mixtures can be separated into the individual stereoisomers by stereoselective synthesis, or by separation of the mixtures by fractional crystallization or chromatography techniques.

A majority of the compounds of the present invention are capable of forming addition salts with inorganic and organic acids. The pharmaceutically acceptable acid salts of the compounds of the present invention are those which form non-toxic addition salts, such as, but not limited to, the hydrochloride, hydrobromide, hydroiodide, nitrate, sulfate or acetate, fumalate, tartrate, succinate, maleate, glucronate, sacchariate, benzoate, methanesulfonate, benzenesulfonate, *p*-toluenesulfonate and pamoate (i.e., 1,1'-methylene-*bis*-(2-hydroxy-3-naphthoate)) salts.

The compounds of the invention which have also acidic groups are capable of forming base salts with various pharmaceutically acceptable cations. Examples of

such salts include the alkali metal or alkaline earth metal salts and particularly, the sodium or potassium salts. These salts are all prepared by conventional techniques. For example, these salts can be easily prepared by treating the aforementioned compounds with an aqueous solution containing the desired pharmaceutically acceptable cation, and then evaporating the resulting solution to dryness, preferably under reduced pressure. Alternatively, they may be also be prepared by mixing together with a lower alkoxide, and then evaporating the resulting solution to dryness in the same manners as before. In either case, stoichiometric quantities of reagents are preferably employed in order to ensure completeness of reaction and maximum production of yields of the desired final product.

In vitro assays

Human cell-based COX-1 assay

Human cell based COX-1 assay is carried out essentially according to a previously described procedure (Grossman *et al.*, *Inflamm. Res.*, 1995, 44, 253). Human peripheral blood obtained from healthy volunteers using Vacutainer is diluted to 1/10 volume with 3.8% sodium citrate solution. The platelet-rich plasma immediately obtained is washed with 0.14 M sodium chloride containing 12 mM Tris-

HCl (pH 7.4) and 1.2 mM EDTA. Platelets are then washed with platelet buffer (Hanks buffer (Ca free) containing 0.2% BSA and 20 mM Hepes). Finally, the human washed platelets (HWP) are suspended in platelet buffer at the concentration of 2.85×10^7 cells/ml and stored at room temperature until use. The HWP suspension (70 μ l aliquots, final 2.0×10^7 cells/ml) is placed in a 96-well U bottom plate and 10 μ l aliquots of 12.6 mM CaCl₂ added. Platelets are incubated with A23187 (final concentration; 10 μ M, Sigma) with test compound (0.1 - 100 μ M) dissolved in DMSO (final concentration; less than 0.01%) at 37°C for 15 min. The reaction is stopped by addition of EDTA (final concentration; 7.7 mM) and TXB₂ in the supernatant 10 quantitated by using a radioimmunoassay kit (Amersham) according to the manufacturer's procedure.

Human cell-based COX-2 assay

Inhibition of COX-2 activity after induction of COX-2 by hIL-1 β

The human cell based COX-2 assay is carried out as previously described 15 (Moore *et al.*, *Inflam. Res.*, 1996, 45, 54). Confluent human umbilical vein endothelial cells (HUVECs, Morinaga) in a 96-well U bottom plate are washed with 100 μ l of RPMI1640 containing 2% FCS and incubated with hIL-1 β (final concentration; 300 U/ml, R & D Systems) at 37°C for 24 hr. After washing, the activated HUVECs are stimulated with A23187 (final concentration; 30 μ M) in Hanks 20 buffer containing 0.2% BSA, 20 mM Hepes and test compound (0.1 nM - 100 μ M) dissolved in DMSO (final concentration; less than 0.01%) at 37°C for 15 min. 6-keto-PGF_{1 α} , stable metabolite of PGl₂ (prostaglandin I₂), in the supernatant is quantitated after adequate dilution by using a radioimmunoassay kit (Amersham) according to the manufacturer's procedure.

25 Inhibition of COX-2 during the induction phase

Confluent human umbilical vein endothelial cells (HUVECs, Morinaga) in a 96-well U bottom plate are washed with 100 μ l of RPMI1640 containing 2% FCS and test compound (0.1 nM - 100 μ M) dissolved in DMSO (final concentration; less than 0.01%), and incubated with hIL-1 β (final concentration; 300 U/ml, R & D Systems) at 30 37°C for 24 hr. After washing, the HUVECs are stimulated with A23187 (final concentration 30 μ M) in Hanks buffer containing 0.2% BSA and 20 mM Hepes at 37°C for 15 min. 6-keto-PGF_{1 α} , a stable metabolite of prostaglandin I₂ (PGl₂), in the

supernatant is quantitated after adequate dilution by using a radioimmunoassay kit (Amersham) according to the manufacturer's procedure.

In vivo assays

Carrageenan induced foot edema in rats

5 Male Sprague-Dawley rats (5 weeks old, Charles River Japan) are fasted overnight. A line is drawn using a marker above the ankle on the right hind paw and the paw volume (V_0) is measured by water displacement using a plethysmometer (Muromachi). Animals are given orally either vehicle (0.1% methyl cellulose or 5% Tween 80) or a test compound (2.5 ml per 100 g body weight). One hour later, the 10 animals are then injected intradermally with λ -carrageenan (0.1 ml of 1% w/v suspension in saline, Zushikagaku) into right hind paw (Winter *et al.*, *Proc. Soc. Exp. Biol. Med.*, **1962**, *111*, 544; Lombardino *et al.*, *Arzneim. Forsch.*, **1975**, *25*, 1629) and three hours later, the paw volume (V_3) is measured and the increase in volume ($V_3 - V_0$) calculated. Since maximum inhibition attainable with classical NSAIDs is 60-15 70%, ED_{50} values are calculated.

Measurement of PGE₂ in inflammatory site and stomach in rats

Determination of PGE₂ synthesized in the inflammatory site is carried essentially according to a previously described method (Opas *et al.*, *Biochem. Pharmacol.*, **1987**, *36*, 547). Foot edema in male Sprague-Dawley rats (5 weeks old) 20 is induced by subplanter injection of 0.1 ml of 1% w/v λ -carrageenan suspension. Animals are sacrificed by cervical dislocation 3 h following carrageenan injection. The foot is amputated, frozen in liquid nitrogen and stored at -80°C until analysis. The stomach of these animals are excised, frozen in liquid nitrogen and stored at -80°C until analysis. The frozen foot is crushed, mixed with 7 ml of ethanol containing 25 10 µg/ml of indomethacin, pulverized in a Waring blender and clarified by centrifugation at 3,000 r.p.m. for 10 min. at 4°C. The frozen stomach is mixed with 7 ml of ethanol containing 10 µg/ml of indomethacin, homogenized by Polytrone and clarified by centrifugation at 3,000 r.p.m. for 10 min. at 4°C. PGE₂ is extracted by a solid-phase extraction devices sold under the trade name of Sep-Pak C₁₈ cartridge 30 (from Waters, Milford, USA) and dried in vacuum. Samples are diluted to a final volume of 0.5 ml with assay buffer (PBS containing 0.1% w/v gelatin) and the level of PGE₂ is quantitated after adequate dilution by using a radioimmunoassay kit (Amersham) according to the manufacturer's procedure. Test compounds are suspended in 0.1% w/v methylcellulose and dosed 1 h before carrageenan injection.

Dexamethasone is dissolved in saline and administered subcutaneously 3 h before carrageenan injection.

Gastric ulceration in rats

The gastric ulcerogenicity of test compound is assessed by a modification of
5 the conventional method (Ezer *et al.*, *J. Pharm. Pharmacol.*, 1976, 28, 655; Cashin *et*
al., *J. Pharm. Pharmacol.*, 1977, 29, 330). Male Sprague-Dawley rats (5 weeks old,
Charles River Japan), fasted overnight, are given orally either vehicle (0.1% methyl
cellulose or 5% Tween 80) or a test compound (1 ml per 100 g body weight). Six
hours after, the animals are sacrificed by cervical dislocation. The stomachs are
10 removed and inflated with 1% formalin solution (10 ml). Stomachs are opened by
cutting along the greater curvature. From the number of rats that show at least one
gastric ulcer or haemorrhaging erosion (including ecchymosis), the incidence of
ulceration is calculated. Animals do not have access to either food or water during
the experiment. The half-ulcerogenic dose (UD_{50}) value, i.e., dose required to induce
15 at least one gastric lesion or one hemorrhagic erosion in 50% of the animals tested,
is calculated by non-linear equation; % Control = $100/(1 + [\text{Dose}]/UD_{50})$.

Data Analysis

Statistical program packages, SYSTAT (SYSTAT, INC.) and StatView
(Abacus Concepts, Inc.) for Macintosh were used. Differences between test
20 compound treated group and control group are tested for using ANOVA. The IC_{50} ,
 ED_{30} or UD_{50} values are calculated from the equation for the log-linear regression line
of concentration (dose) versus percent inhibition.

In these testings, some compounds indicated low IC_{50} values, in the range of
0.01 to 1.0M.

25 The compounds of the formula (I) of this invention can be administered via
either the oral, parenteral or topical routes to mammals. In general, these
compounds are most desirably administered to humans in doses ranging from 0.01
mg to 100 mg per kg of body weight per day, although variations will necessarily
occur depending upon the weight, sex and condition of the subject being treated, the
30 disease state being treated and the particular route of administration chosen.
However, a dosage level that is in the range of from 0.1 mg to 10 mg per kg of body
weight per day, single or divided dosage is most desirably employed in humans for
the treatment of above-mentioned diseases.

The compounds of the present invention may be administered alone or in combination with pharmaceutically acceptable carriers or diluents by either of the above routes previously indicated, and such administration can be carried out in single or multiple doses. More particularly, the novel therapeutic agents of the
5 invention can be administered in a wide variety of different dosage forms, i.e., they may be combined with various pharmaceutically acceptable inert carriers in the form of tablets, capsules, lozenges, trochees, hard candies, powders, sprays, creams, salves, suppositories, jellies, gels, pastes, lotions, ointments, aqueous suspensions, injectable solutions, elixirs, syrups, and the like. Such carriers include solid diluents
10 or fillers, sterile aqueous media and various nontoxic organic solvents, etc. Moreover, oral pharmaceutical compositions can be suitably sweetened and/or flavored. In general, the therapeutically-effective compounds of this invention are present in such dosage forms at concentration levels ranging 5% to 70% by weight, preferably 10% to 50% by weight.

15 For oral administration, tablets containing various excipients such as microcrystalline cellulose, sodium citrate, calcium carbonate, dipotassium phosphate and glycine may be employed along with various disintegrants such as starch and preferably corn, potato or tapioca starch, alginic acid and certain complex silicates, together with granulation binders like polyvinylpyrrolidone, sucrose, gelatin and
20 acacia. Additionally, lubricating agents such as magnesium stearate, sodium lauryl sulfate and talc are often very useful for tabletting purposes. Solid compositions of a similar type may also be employed as fillers in gelatine capsules; preferred materials in this connection also include lactose or milk sugar as well as high molecular weight polyethylene glycols. When aqueous suspensions and/or elixirs are desired for oral
25 administration, the active ingredient may be combined with various sweetening or flavoring agents, coloring matter or dyes, and, if so desired, emulsifying and/or suspending agents as well, together with such diluents as water, ethanol, propylene glycol, glycerin and various like combinations thereof.

For parenteral administration, solutions of a compound of the present
30 invention in either sesame or peanut oil or in aqueous propylene glycol may be employed. The aqueous solutions should be suitably buffered (preferably pH>8) if necessary and the liquid diluent first rendered isotonic. These aqueous solutions are suitable for intravenous injection purposes. The oily solutions are suitable for intra-articular, intra-muscular and subcutaneous injection purposes. The preparation of all

these solutions under sterile conditions is readily accomplished by standard pharmaceutical techniques well-known to those skilled in the art. Additionally, it is also possible to administer the compounds of the present invention topically when treating inflammatory conditions of the skin and this may preferably be done by way
5 of creams, jellies, gels, pastes, ointments and the like, in accordance with standard pharmaceutical practice.

The following examples contain detailed descriptions of the methods of the preparation of compounds of formula I. These detailed descriptions fall within the scope, and serve to exemplify, the above described General Synthetic Procedures
10 which form part of the invention. These detailed descriptions are presented for illustrative purposes only and are not intended as a restriction in the scope of the invention.
